## Linear regression

In this tutorial we'll learn:

- how to merge datasets
- how to fit linear regression models
- how to split data into test and train sets
- how to tune our models and select features

## Data preparation

We're working with the Capital Bikeshare again this week, so start by reading in usage, weather, stations.

#### Merging data

We have three related datasets to work with, but we can't really get started until they're combined. Let's start with usage and weather. The usage dataframe is at the resolution of the hour, while the weather data are at the resolution of a day, so we know we're going to have to either duplicate or compress data to merge. I vote compress, let's summarize!

```
head(usage)

#### The lm() function

The function for creating a linear model in R is lm() and the primary arguments are formula and data. Formulas in R are a little funny, instead of an = sign, they are expressed with a  $\sim$ . Let's fit the model we saw in the lecture notes:  $rentals = \beta_0 + \beta_1 * crossing$ . There's a little snag we have to take care of first. Right now we've got repeated measures *i.e.* one measurement per day, so we need to aggregate again this time over date.

```

                                                                                              0.06
                                       40
```

The attributes() function can be called on just about any object in R and it returns a list of all the things inside. It's a great way to explore objects and see what values are contained inside that could be used in other analysis. For example, extracting the residuals via model\$residuals is useful if we want to print diagnostic plots like those above.

Leverage

When we run summary() on the 1m object, we see the results. The *Call* section just prints back the model specification, and the *Residuals* section contains a summary of the distribution of the errors. The fun stuff is in the *Coefficients* section. In the first row contains the covariate names followed by their estimates, standard errors, t- and p-values. Our model ends up being rentals = 28 + 0.50(crosswalks) which means that the average number of rentals when there are no crosswalks is 28, and the average increases by 1 rental for every two additional crosswalks.

We can fit regressions with multiple covariates the same way:

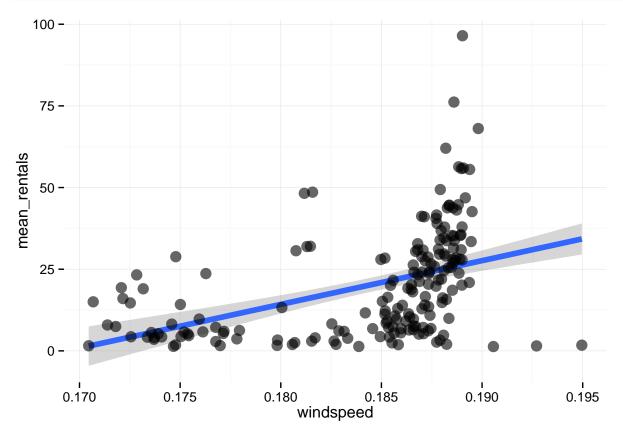

Fitted values

```
# lets include windspeed this time
rentals_multi = data %>%
  group_by(station_start) %>%
  summarize(mean_rentals = mean(no_rentals),
```

```
crossing = mean(crossing),
    windspeed = mean(windspeed))
head(rentals_multi)
```

```

```

The model coefficients changed quite a lot when we added in wind speed. The intercept is now negative, and the wind speed coefficient is huge! When interpreting coefficients, it's important to keep the scale in mind. Wind speed ranges from 0.05 to 0.44 so when you multiply 2036 by 0.05 for example, you end up with about 102, which is within the range we'd expect.

Let's try one more, this time we'll include a factor variable.

```
rentals_multi = data %>%
  group_by(station_start, is_work_day) %>%
  summarize(mean rentals = mean(no rentals),
            crossing = mean(crossing),
            windspeed = mean(windspeed))
head(rentals multi)

```

The output looks a little funny now. There's a term called factor(is\_work\_day)1, what does that mean? Factors are category variables and their interpretation is relative to a baseline. Our factor is\_work\_day only

has two levels, 0 and 1, and R sets 0 to the baseline by default. So the interpretation of that term is that we can expect about 17 additional rentals when it is a work day (i.e. is\_work\_day == 0) and the other variables are fixed.

#### Train and test data

For all analyses in this class we'll need to divide our data into train and test sets. We'll do this using a package called *caret*. Check out this nice overview for more details.

## The caret package

The *caret* package in R contains helper functions that provide a unified framework for data cleaning/splitting, model training, and comparison. I highly recommend the optional reading this week which provides a great overview of the *caret* package.

```
install.packages('caret', dependencies = TRUE)
library(caret)
set.seed(1234) # set a seed
```

Setting a seed in R insures that you get identical results each time you run your code. Since resampling methods are inherently probabilistic, every time we rerun them we'll get slightly different answers. Setting the seed to the same number insures that we get identical randomness each time the code is run, and that's helpful for debugging.

#### Splitting data into test and train sets

In data mining we're interested in creating models for prediction, and we'll assess the quality of our models by quantifying their prediction accuracy. To measure prediction quality, we hold out a portion of our data called the *test* set. The *training* data is used to build the model.

```
## Resample1
## [1,] 14
## [2,] 25
## [3,] 27
## [4,] 61
## [5,] 71
## [6,] 83
```

```
training_set = data[in_train, ]
testing_set = data[-in_train, ]
dim(training_set)
```

```
## [1] 73977 154
```

```
dim(testing_set)
```

```
## [1] 24657 154
```

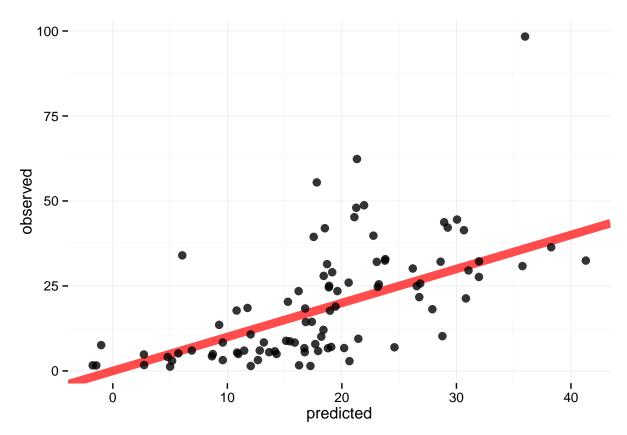

Note: I recommend doing all data processing and aggregation steps before splitting out your train/test sets.

## Fitting / Training

A workhorse function in the *caret* package in the train function. This function can be used to evaluate performance parameters, choose optimal models based on the values of those parameters, and estimate model performance. For regression we can use it in place of the lm() function. Here's our last regression model using the train function.

```
## Resample1
## [1,] 3
## [2,] 17
## [3,] 18
## [4,] 41
## [5,] 44
## [6,] 47
```

```
## Linear Regression
##
## 278 samples
##
     4 predictor
## No pre-processing
## Resampling: Bootstrapped (25 reps)
##
## Summary of sample sizes: 278, 278, 278, 278, 278, 278, ...
##
## Resampling results
##
##
    RMSE
              Rsquared
                         RMSE SD
                                   Rsquared SD
     14.8344 0.2514065 1.143292 0.05124707
##
##
##
```

Our prediction accuracy is not so great for this model. The RMSE is about 31 which means that on average the predictions are off by about 31 rentals.

## Feature Selection

Next time!

## Project tips

We saw this issue before when we constructed our SLR.

 $\label{eq:model_data} $$ model_data = data \%>\% \ group\_by(station\_start, weekday, season\_code, is\_holiday, is\_work\_day, weather\_code) \%>\% \ summarize(no\_rentals = mean(no\_rentals)) $$ head(model_data)$
